FACTORS THOSE INFLUENCE IN SELF-EFFICACY OF BREASTFEEDING: AN INTEGRATIVE REVIEW

ABSTRACT
Objective: to evaluate the available evidence in scientific articles about the factors that influence the self-efficacy of breastfeeding. Method: integrative review, based on the following research question << What factors influence the self-efficacy of breastfeeding? >>, in databases PUBMED and LILACS. Inclusion criteria were: research articles with evidence level 1-4 in the standings on seven levels, available online, in full and free of charge, in English, Portuguese or Spanish, and exclusion: no summary articles in the database or incomplete. Results: the analysis showed that factors positively or negatively affect the self-efficacy of breastfeeding. Conclusion: the study highlights the importance of the network of family, as the mother needs encouragement and support of his family and community. Professionals and institutions must draw interventions aimed at changing the model of care, and promote health through effective assistance to care for both mother and child. Descriptors: Breastfeeding; Self-Efficacy; Nursing; Women's Health, Child Health.

RESUMO
Objetivo: avaliar as evidências disponíveis nos artigos científicos a respeito dos fatores que interferem na autoeficácia da amamentação. Método: revisão integrativa, tendo como base o seguinte questionamento de pesquisa << Quais os fatores que interferem na autoeficácia da amamentação? >>, nas bases de dados LILACS e PUBMED. Os critérios de inclusão foram: artigos de pesquisas com nível de evidência de 1 a 4 na classificação em sete níveis, disponíveis online, na íntegra e de forma gratuita; em inglês, português ou espanhol; e de exclusão: artigos sem resumo na base de dados ou incompletos. Resultados: a análise mostrou fatores que interferem positivamente ou negativamente na autoeficácia de amamentação. Conclusão: destaca-se a importância da rede de familiares, pois a mãe necessita de incentivo e suporte da sua família e comunidade. Os profissionais e as instituições devem traçar intervenções que visem mudanças no modelo da assistência, além de promover saúde por meio de uma assistência eficaz para cuidar do binômio mãe-filho. Descriptors: Aleitamento Materno; Autoeficácia; Enfermagem; Saúde da Mulher; Saúde da Criança.

INTRODUCTION

Breastfeeding results in a positive impact on maternal health, and provide a complete food and protection for the child. Breastfeeding (BF) is an important factor in reducing child mortality, as estimates suggest that the increased prevalence of breastfeeding at one year of life, in all countries, can save up to 1.3 million infants worldwide.1

Besides being considered the best food for babies, breast milk (LM) is also recognized for offering advantages in strengthening the bond between mother and baby. Linking from mother to child is not innate and breastfeeding is an opportunity to install this link or deepen it.

Thus, it is necessary that the woman has elements that can positively influence your choice to breastfeed, among them the confidence in the AM, which can be represented by belief or expectation of the woman that she has the knowledge and skills to breastfeed your baby successfully. Soon, the woman’s belief that she can breastfeed, i.e., self-efficacy must occur before breastfeeding is undertaken.3

Research shows that 27% of women with low levels of confidence in breastfeeding during antenatal AM discontinued within the first week postpartum. Still, women with low levels of confidence in the PM were 3.1 times more likely to stop breastfeeding than those who had total confidence. So women need to believe that they can adhere to healthy behaviors so therefore can undertake the necessary efforts to reach them.3

It is believed that mothers understand the perception of self-efficacy in relation to breastfeeding allows for professional reflection and questioning of what can be done to minimize and/or reduce rates of weaning. Building evidence regarding attitudes of women towards breastfeeding may lead to the development of strategies for the promotion, protection and support of breastfeeding.

OBJECTIVE

• To evaluate the available evidence in scientific articles about the factors that influence the self-efficacy of breastfeeding.

METHOD

Study integrative literature review in order to gather and synthesize research results on a defined topic or issue in a systematic and orderly. Followed the steps: identification of the subject, the research question selection and definition of objectives, establishing inclusion and exclusion criteria, study selection, preparation of information to be extracted from articles, review the evidence and analysis (categorization), and discussion presentation of the synthesis of knowledge evidenced in the analyzed articles.4

To guide this study, the research question was formulated: What factors influence the self-efficacy of breastfeeding? A literature search was performed in electronic databases Medline Public (PubMed) using the MeSH Terms “breastfeeding” and “self-efficacy” in the database and Latin American and Caribbean Health Sciences (LILACS) using the keywords “breastfeeding” and “self-efficacy”.

The survey of the studies took place in October 2012. To select them, the inclusion criteria were: research articles with evidence level 1-4 in the standings on seven levels, 5 available online, in full and free, in English, Portuguese or Spanish. Exclusion criteria were: no summary articles in the database or incomplete.

Initially, 106 studies were found, of which 10 met the inclusion criteria. It is noteworthy that in the LILACS database did not contain articles on the topic.

After thorough reading of the selected studies was completed an instrument containing: reference, country where the study was conducted, subarea of knowledge, purpose and methodology of the study, level of evidence and key findings of the study.

To minimize possible measurement bias studies (misinterpretation of results and design), two researchers had read the articles and complete the instrument independently, which were subsequently compared. There were no differences regarding the evaluation of publications.

The studies were classified according to the seven levels of evidence described by Melnyk and Fineout-Overholt.5

RESULTS

Most of the studies was published in 2006 (30%) and 2008 (30%), followed by the year of 2009 (20%). The United States of America (30%) concentrated most of the publications, followed by Canada, the Netherlands and Australia (20% each). As for sub-areas of knowledge, most belonged to 40% and nursing (Professional (40%), followed by medicine (20%). For the design of the studies, 4 (40%) were randomized clinical trial, 5 (50%) and 1 cohort (10%) if the control. According to the classification of the level of evidence the5 found:
four studies with evidence level 2 and six with 4 level.

Figure 1 presents the studies analyzed, sorted by authors, purpose, outline and main results (Figure 1).

**Figura 1.** Corpus da revisão integrativa. LILACS, PUBMED. 2012.
The analysis of the studies (n = 10) enabled the identification of factors that influence positively or negatively affect breastfeeding self-efficacy (Figure 2).

Among the factors that affect positively on self-efficacy, are: good socioeconomic and demographic conditions; experience and/or experience positive AM; practice AME postpartum; family support; positive cultural influence on breastfeeding; access to information; decision and intention to breastfeed; type of birth and its positive living; multiparity; and conducting prenatal.

But among the factors that contribute negatively are: maternal concern about the quality and quantity of milk; difficulties early in the AM; stress, anxiety and depression; sore nipples during breastfeeding; use of formula milk as a complement or substitute for breast milk; and return of women to the labor market.

The socioeconomic and demographic characteristics such as maternal age, education and income had an influence on self-efficacy of breastfeeding. Maternal age is related to greater duration of EBF. Compared to younger women, older mothers maintain the practice for longer.

The level of education is an aspect that can affect maternal motivation to breastfeed, because low-income women seek less prenatal service or start late this monitoring.

Mothers with experience and/or positive experiences of breastfeeding have higher self-efficacy and fewer difficulties, concerns and questions related to breastfeeding, even though each individual experiences. In contrast, the inexperience can be a contributing factor to increased attention and care of the child, seeming safety of care needed with him.

Exclusive breastfeeding the child after birth also influences positively on maternal confidence. By offering only the LM’s mother realizes that it is sufficient for the growth and development of the child and starts to want to breastfeed for six months or more.

The fact that the mother receives support from family members, especially the husband or partner and grandparents, has a positive influence on self-efficacy of breastfeeding. For this support materializes, family members should be involved in promoting the AM still in the hospital so they can support the mother and help the mother feel able to breastfeed.

Still, access to information, especially guidelines for health professionals, demonstrated influence on mother’s confidence in breastfeeding. The healthcare team should reassure parents and family appropriate guidance about the benefits of breastfeeding for the mother to the child, for the family and for society. The information shall seek the solution of problems as well as preventing and helping the mother to overcome the difficulties that the process of breastfeeding can cause, can make the mother more confident.
Childbirth is seen, in most cases, as a significant and remarkable event in family life and his experiences establishes positive feelings of pleasure and sense of efficacy, indicating better ability to cope and manage the difficulties with breastfeeding. The performance of cesarean section was one of the main risk factors for supply of other liquids to the neonate and is related to difficulties in breastfeeding initiation. 23

As for parity, the analyzed studies show that women remain multiparous EBF for a longer period. Accordingly, some authors claim that mothers wean early and keep the firstborn AM longer the greater the number of children. 16

Performing prenatal also promotes self-efficacy and practice of breastfeeding, because that benefits accompanying the preparation of the mother and family for breastfeeding. Thus, prenatal care contributes to the success of breastfeeding, and women should be informed of the benefits of this practice, the disadvantages of using other milks and techniques of breastfeeding, to increase the skill and confidence of the mother. 24

The maternal concern regarding the quantity and quality of milk may be a factor that impairs the self-efficacy of breastfeeding. The most frequent reason that generates seizures in the mother is associated with low milk production or with the belief that their milk is weak complaint related to insecurity or lack of knowledge about the act of nursing mothers to breastfeed. 25

The difficulties with the start of PM can produce a negative effect in this practice and also in the care of infants. May be associated with delayed first feeding, introduction of milk supplements and the use of bottles for this offering, which may cause thus weaning the child. 26

The psychological distress can make room for states of stress, anxiety and depression that can accompany the mother during the postpartum period and interfere with breastfeeding self-efficacy. These factors tend to decrease over time, but it is necessary to identify symptoms before discharge from the AC, in order to prevent those states from becoming chronic and impairing AM. 27

The presence of pain while breastfeeding can interfere with maternal confidence, it may be due to inadequate grip and stance. The guidelines of health professionals are needed; it may lessen the discomfort and maintain milk production. 28

Therefore, mothers can opt for change in feeding their children to feel less confident to breastfeed. The formula is used as the second best choice of food and easiest method, with no pain or discomfort for the mother. Massive advertising campaigns carried out in the past by industry breastmilk substitutes also affect the perception of safety in the use of formulas, which seems to generate tolerance and permissiveness regarding its use. 29

The maternal concern about having to return to work difficults to keep breastfeeding and maternal self-efficacy in performing this practice. It is noteworthy, therefore, the importance of compliance with the policies of protection of breastfeeding after delivery, in order to increase the prevalence of breastfeeding, even after the mother returns to work. 30

CONCLUSION

Exclusive breastfeeding depends on the mother’s desire to breastfeed, the role of health professionals and support that women receive from people close to her. Take up the commitment to promote, protect and support breastfeeding, as this may contribute to increased self-efficacy of breastfeeding mothers and lead, in the medium and long term, to reduce rates of early weaning and prolonged period of AME.

The study highlights the possibility of actions of health education developed by nursing during prenatal consultations, coupled with the promotion of breastfeeding in the delivery room or in the first hour of life. Still, the support postpartum rooming-in and monitoring the maintenance of breastfeeding for checkups. Moreover, it is necessary to invest in research designs that present strong evidence about the topic investigated, especially in health practice.
