KNOWLEDGE, ATTITUDES AND PRACTICES IN HEALTH OF THE RURAL AREA ELDERS

Carla Weber Peters1, Celmir Lange2, Marcos Aurélio Matos Lemões3, Gabriele Bester Hermès4, Caroline de León Linck5, Clarice de Medeiros Carriêre6

ABSTRACT

Objective: to identify the knowledge, attitudes and practices in health of elderly people living in rural areas.

Method: this is a bibliographical study, type integrative, carried out in the MEDLINE, LILACS, Web of Science, Scopus and SciELO virtual libraries. The original qualitative studies, available in full and published between 2013 and 2017, were considered. Data on location and year of publication, objectives, methods and results were analyzed. The results were presented in the form of figures.

Results: eight studies published in international journals were analyzed, resulting in the categories. Conclusion: it is verified that the health knowledge of the elderly living in rural areas is fragile, mainly, in the identification of risk factors and signs and symptoms of diseases and injuries. Health attitudes and practices reveal the difficulty of adherence / understanding of health promotion actions and prevention of diseases and injuries, possibly due to a lack of culturally congruent care.

Descriptors: Knowledge, Attitudes and Practice In Health; Old Man; Older Than 80 Years or Older; Rural Population; Countryside; Nursing.

RESUMO

Objetivo: identificar os conhecimentos, atitudes e práticas em saúde de idosos residentes em zona rural.

Método: trata-se de estudo bibliográfico, tipo revisão integrativa, realizado nas bases de dados MEDLINE, LILACS, Web of Science, Scopus e na biblioteca virtual SciELO. Consideraram-se os estudos originais qualitativos, disponíveis na integra e publicados no período de 2013 a 2017. Analisaram-se os dados referentes à local e ano de publicação, objetivos, métodos e resultados. Apresentaram-se os resultados em forma de figuras.

Resultados: analisaram-se oito estudos publicados em periódicos internacionais resultando em categorias. Conclusão: constata-se que os conhecimentos em saúde dos idosos residentes em zona rural são frágeis, principalmente, no que se refere à identificação de fatores de risco e sinais e sintomas de doenças e agravos. As atitudes e práticas em saúde revelam a dificuldade de adesão/compreensão de ações de promoção da saúde e prevenção de doenças e agravos, possivelmente devido a falta de um cuidado culturalmente congruente.

Descritores: Conhecimentos, Atitudes e Prática em Saúde; Idoso; Idoso de 80 Anos ou Mais; População Rural; Zona Rural; Enfermagem.

RESUMEN

Objetivo: identificar los conocimientos, actitudes y prácticas en salud de ancianos residentes en zona rural.

Método: se trata de estudio bibliográfico, tipo revisión integrativa, realizado en las bases de datos MEDLINE, LILACS, Web of Science, Scopus y en la biblioteca virtual SciELO. Se consideraron los estudios originales cualitativos, disponibles en su totalidad y publicados en el periodo de 2013 a 2017. Se analizaron los datos referentes a la ubicación y año de publicación, objetivos, métodos y resultados. Se presentaron los resultados en forma de figuras.

Resultados: se analizaron ocho estudios publicados en periódicos internacionales resultando en las categorías. Conclusión: se constata que los conocimientos en salud de los ancianos residentes en zonas rurales son frágiles, principalmente, en lo que se refiere a la identificación de factores de riesgo y signos y síntomas de enfermedades y agravios. Las actitudes y prácticas en salud revelan la dificultad de adhesión / comprensión de acciones de promoción de la salud y prevención de enfermedades y agravios, posiblemente debido a la falta de un cuidado culturalmente congruente.

Descripciones: Conocimientos, Actitudes y Práctica en Salud; Anciano; Anciano de 80 o Más Años; Población Rural; Medio Rural; Enfermería.
INTRODUCTION

It is known that population aging is a reality in developed and developing countries, since most people can expect to live 60 years or more, and it is estimated that, by 2050, there will be two billion elderly people around the world, with 80% living in low and middle-income countries. It is estimated that in Brazil, due to the decrease in the number of births and the increase in life expectancy, the population in this age group by 2070 will correspond to 35% of the total number of inhabitants, surpassing the indicator for the set of developed countries.

It is noted that this demographic change poses a challenge to science, nurses and other health professionals regarding the formulation and implementation of public policies, while requiring, from the social and health systems of the countries, a preparation to respond positively to the aging of the population in order to provide the elderly with an old age with quality and life satisfaction.

For this, it is fundamental to take into account the social and cultural factors of the context in which the elderly are inserted, so that the actions of health promotion and prevention of diseases and injuries are, in fact, directed to their real needs, because the aging process is heterogeneous and individual. It is added, although there is a decline in the health of the elderly of natural order, which each person ages in the way coherent with the trajectory of life traversed over time.

In this sense, it should be pointed out that residing in a rural or urban area has differences that can significantly influence the lives of the elderly due to the specific characteristics of the localities that determine the people’s historical, social and cultural life.

Individuals such as the predominance of domestic activities, agriculture and livestock, difficulties in access to health and transportation services, low economic conditions and social isolation are shared by elderly people living in rural areas. It is necessary to better evidence such singularities in order to constitute guiding axes for the planning, implementation, evaluation and (re) formulation of health policies, programs and actions, in order to promote effective and effective care, based on principles of integral and equity.

From the above, and considering the recent research on older people under new perspectives, although the majority focused on those living in urban areas, how fundamental are the studies on the knowledge, attitudes and practices of elderly people living in rural areas with a view to culturally consistent care.

OBJECTIVE

- To identify the knowledge, attitudes and practices in health of elderly people residing in rural areas.

METHOD

It is a bibliographical study, type integrative review (IR) with the purpose of synthesizing and analyzing the scientific production on the knowledge, attitudes and practices in health of elderly people living in rural areas in the national and international scenarios.

In order to extract data and incorporate evidence into health and nursing, the following steps are contemplated: formulation of the theme and the guiding question; definition of the criteria for inclusion and exclusion of studies, search in the literature, categorization of studies included in the review; evaluation of studies; interpretation of results and synthesis of knowledge.

The guiding question in this IR is: “What are the knowledge, attitudes and practices in the health of elderly people living in rural areas at national and international levels?”

The scientific productions were searched in the databases: Online System of Search and Analysis of Medical Literature (MEDLINE), Latin American and Caribbean Literature in Health Sciences (LILACS), Web of Science, Scopus and in the virtual library Scientific Electronic Library Online (SciELO) from the following strategy: Health Knowledge, Attitudes, Practice AND Aged OR Aged 80 and over AND Rural Population OR Rural Areas.

The original qualitative studies that dealt with the health knowledge, attitudes and practices of elderly people living in rural areas, available in full, published between 2013 and 2017 in Portuguese, English or Spanish were considered. This period was chosen because it was intended to seek the most recent scientific productions in the literature, which could contribute to the quality of health policies, programs and actions directed at the elderly living in rural areas. Publications of congress annals, abstracts and letters to the editor were excluded.

The categorization and evaluation of the studies were carried out after the scientific productions were searched, and the titles and abstracts were considered, respectively, and when they did not make clear the relation with the subject matter, the inclusion and
exclusion criteria. A new evaluation of the studies was carried out by means of the integral reading aiming to refine the sample based on the guiding question.

The results of the search process of the productions are presented in Figure 1.

The study’s commitment to the ethical aspects referring to the citation of authors of scientific publications, as provided for in Law No. 9,610 of February 1, 1998, which deals with copyright.  

Figure 1- Flowchart of the stages of the integrative review. Pelotas (RS), Brazil, 2017.

The analysis of the eight studies included in the integrative review was carried out in a critical and reflexive way, which is presented, through figure 2.
Knowledge, attitudes and practices in health…

It can be seen in Figure 2 that scientific production related to health knowledge, attitudes and practices of elderly people living in rural areas presented a similar distribution among the years of publication, and in the years of 2013, 2014 and 2016 there were two publications, respectively.

All articles included in the IR were published in seven international and interdisciplinary journals, so they were all available in the English language; the Journal of Cross-Cultural Gerontology focuses on aging in cultural contexts and Rural Remote Health and The Australian journal of rural health, rural health, and The Australian journal of rural health, there have been two publications from 2013 to 2017.

Three countries were studied in Australia, two in the United States, in Scotland, 8 in Colombia, 11 in Uganda 13 and none in Brazil, representing a gap in scientific knowledge about health knowledge, attitudes and practices of elderly people living in rural areas, especially in the national scenario.

The objectives, methods and main results of the articles included in the IR are shown in figure 3 below.

Figure 3 - Presentation of articles on health knowledge, attitudes and practices of elderly residents in rural areas according to the objectives, methodology and main results.

Figure 3 shows the proposed objectives, based on the analysis of the scientific production on the knowledge, attitudes and health practice of elderly people living in rural areas, who, of the eight studies, only two assess the conceptions of the elderly with \(^\text{12,14}\) while others address specific issues related to diseases, hearing problems and use of hearing aids, depression, heart attack, type II diabetes, systemic arterial hypertension, and sleep sickness.\(^\text{7,11,13}\)

Two studies of mixed method, \(^\text{7,8}\) quantitative and qualitative, and six studies of qualitative method were found.\(^\text{9,14}\) Among the techniques of data collection, the use of interviews in the eight studies,\(^\text{7,14}\) among them, the semi-structured, in six studies,\(^\text{7,12}\) and in three, the focus group discussion technique \(^\text{8,11,13}\) was also present. The in-depth interview\(^\text{13}\) and the health vignettes\(^\text{9}\) were used in one study each. For the selection of participants, snowball, known as a snowball sample, was used in four studies included in this IR.\(^\text{9-13}\)

Data analysis was carried out in all the analyzed studies, the codification and thematic categorization of the collected data, \(^\text{7,14}\) however, they diversified as to the type of
analysis used, evidencing the comparative, the inductive and the thematic. The software for the treatment and analysis of qualitative data was used in four surveys: o QSR® N-Vivo10® 8,11 and Maxqda®. 13

DISCUSSION

It is shown in the results of RI that the number of scientific productions on the knowledge, attitudes and health practice of elderly people residing in rural areas, from 2013 to 2017, is restricted, emphasizing the need for new studies that mobilize the international and especially national academic debate. It is believed that aging must be understood in different contexts and, as regards the living and health conditions of these elderly people, in Brazil, there is a lack of data that can contribute to the improvement of care. 

It is also shown in the results that most of the publications were indexed in the Scopus database, which allows a comprehensive view of the world scientific production of several fields of knowledge, which explains the publications included in this research proceed from periodicals interdisciplinary and international studies of relevance to Nursing and other health professions.

It should also be pointed out that the expressive number of interviews, especially the semi-structured interviews carried out to collect data between the analyzed studies, may be related to the fact that they have 60 years or more as participants. It is necessary to take into account, when conducting studies with the elderly, the limitations related to aging, which can influence the understanding of the research questions; In this way, the semi-structured interview is usually preferred in these cases because of its greater flexibility, which allows us to resume and reformulate questions as necessary.

The following categories were identified based on the guiding question and the objective of this research: Health attitudes and practices of the elderly living in rural areas; The importance of health education for knowledge, attitudes and practices in the health of the elderly living in rural areas and barriers to knowledge; attitudes and practices in the health of elderly people living in rural areas.

Health attitudes and practices of elderly people living in rural areas

It is believed that thinking about the health attitudes and practices of the elderly living in rural areas is undoubtedly to reflect on the ways of life and the singularities related to the lived and experienced reality. The concept of health of these people is generally described as the ability to carry out the activities of daily living, especially work in the field, even in cases of illness or disability, compared to agricultural machinery that can be repaired when spoils.

It can be seen that, although elderly people living in rural areas generally do not have healthy living habits, with a view to promoting health and preventing diseases and injuries, at the time they perceive patients, that is, when they can not more to develop their activities of daily living, follow the guidelines of health professionals regarding drug therapy and lifestyle change, especially in relation to the practice of physical activities and eating habits.

It should be pointed out that older people were more likely to follow preventive measures, thus suggesting that, as one grows older, adherence to physical exercise and food adequacy due to inherent health needs to the aging process increase.

In the study on the influence of the rural social and cultural context in the treatment of type II diabetes, in order to understand the social processes constructed, people living in the rural area, including the elderly, have the capacity to adapt in accordance with the limitations imposed by the disease in search of autonomy and self-sufficiency, that is: they manage to normalize their self-care behaviors through the construction of meanings about their lives in a way that is congruent with the specificities of the rural area.

It thus becomes apparent that diabetes management behaviors as well as other diseases in rural areas result from cultural, social, political and economic factors that are concentrated over time. It is recalled that there are many positive aspects of rural life, which can contribute to the health attitudes and practices of the elderly, such as contact with nature and maintenance of physical condition, and negative aspects such as working conditions, stress and violence.

Based on the above, the health attitudes and practices of elderly people living in rural areas seem to be directly related to the social and cultural context and reveal the difficulty of adherence/understanding of health promotion and prevention actions and, especially, by only understanding themselves as patients when they are no longer able to carry out their daily and work activities. This may be related to the lack of culturally congruent care. In contrast, identifying themselves as patients tend to develop positive attitudes of self-management of
Illness in order to resume their life routines as soon as possible.

**Importance of health education for the knowledge, attitudes and practice in the health of the elderly living in rural areas**

There is limited awareness of risk factors for diseases and conditions, as well as the ability to recognize symptoms is greatly reduced among elderly people living in rural areas. This limitation is related, directly, to the lack of dissemination of information in relation to the health-disease-care process that contribute to knowledge and, therefore, to health attitudes and practice. 9-11,13

In a study on the prevention, detection, management and control of systemic arterial hypertension (SAH), developed in urban and rural areas in Colombia, for example, the elderly had little understanding of the disease, probably because none of the participants recalled the implementation of health education with a focus on SAH, while many participants reported the lack of information and proximity to health professionals.11

Similarly, another study of the symptoms of heart attack and decision-making revealed that women who were 65 years of age or older residing in rural areas of the Midwest of the United States with difficulty in recognizing these symptoms had no proximity to the subject and consequently sought help late. However, it was determined that the majority of the participants had an easy way to correctly recognize the symptoms of cardiovascular disease due to personal experiences and participation in community classes, reflecting positively on health attitudes and practice. 9

In this context, the importance of health education planning and development is highlighted, with a view to promoting health and preventing diseases and diseases, through a dialogue between health professionals and the elderly who are under their care, allowing the construction of knowledge together and from these people. It is essential to share information, as well as the consideration of the social and cultural factors of the context in which the elderly are inserted, to help them adjust and optimize their ways of life, both before and after, in the occurrence of diseases and injuries. 8,9

This relevance is also evident in the study carried out in Scotland, which explored the perception and experiences of the elderly with the use of new hearing aids, emphasizing the informational needs of older people before and after adaptation to the orthosis, according to the report of the participants. 8

As well as in the study carried out in Australia, which investigated the influence of rural culture on the management of type II diabetes, showing that the lack of knowledge about services or related health information negatively influences the care management processes in patients with diabetes.10

Finally, it is pointed out that in order to strengthen the importance of health education for the knowledge, attitudes and practice in the health of elderly people living in rural areas, the study related to memories of African elderly about sleep disease, which emphasized the indispensable sharing of information between health professionals and the elderly. Through the scenario of resistance and fear of new health interventions, such as the development of the medical campaign of Médecins Sans Frontières Spain (2010-2011), based on the historical context and point of view of those who had experienced the disease in the past, for the construction of knowledge in the community, thus for the increase of trust.13

It is understood, therefore, that health education can contribute in an unequaled way in the construction and strengthening of positive attitudes and health practices of the elderly living in rural areas as in the adhesion to actions of health promotion and prevention of diseases and injuries, in the identification of risk factors early and in the understanding of the treatments proposed by the health teams, increasing the knowledge of the elderly about health care. The publications analyzed highlight the importance of conducting health education activities in a way that approaches the way of life of this population by valuing their beliefs, values and popular knowledge.

**Barriers to knowledge, attitudes and practice in the health of elderly people living in rural areas.**

It is difficult to access health services at different levels of technological complexity as the main barrier to health knowledge, attitudes and practices of elderly people living in rural areas. This difficulty is related to the lack of information, the low economic condition, the distrust of the health system and, above all, the scarce availability of health services, as well as the long distances to be covered or transportation problems, such as such as inexistence and high cost when existing.9,11

In this study, it was demonstrated that, due to the fact that the elderly women living in rural areas of the Midwest of the United States were resistant to calling the emergency mobile service (ambulance), it would be time...
Knowledge, attitudes and practices in health...

Conclusions

It can be seen in this integrative review that the scientific production on knowledge, attitudes and practices in the health of elderly people living in rural areas is still incipient, especially in the national scenario. The publications indicate that the knowledge of these elderly people in relation to the health-disease-care process is fragile, especially in relation to the identification of risk factors and signs and symptoms of diseases and injuries. As well as, that their attitudes and practices in health reveal the difficulty of adherence / understanding of actions of health promotion and of prevention of illnesses and diseases, possibly due to lack of culturally congruent care.

It was also identified that one of the possibilities for building and strengthening positive attitudes and health practices of elderly residents in rural areas with a view to expanding and qualifying their knowledge is health education, developed by health professionals in a shared way with the population, approaching and valuing the local culture. In addition, the construction of a culturally congruent care may also contribute
to the transposition of the barriers identified in the selected scientific production, such as the difficulties of access to health services and linguistic diversity.

Finally, the need to increase and qualify nurses and other health professionals regarding social and cultural diversity with the aim of improving access to health services and, consequently, the provision of a culturally consistent care for the elderly living in rural areas.
