ASPECTS OF GESTATION AND PUERPERIUM OF WOMEN WITH MENTAL DISORDERS

Camila Soares Teixeira1, Taciana Lemos Barbosa2, Vivian Silva Lima Marangoni3, André Luiz Machado das Neves4, Munique Therense5

ABSTRACT

Objective: to identify the evidence on the aspects of gestation and puerperium of women with mental disorders in Brazil. Method: this is a bibliographical study, an integrative review, of articles published between 1980 and 2018. A search was carried out in the LILACS, MEDLINE, BDENF and the SciELO · Scientific Electronic Library Online. Results were presented in figures. Results: 19 articles were selected and, after the critical reading, four thematic categories were highlighted: Implications for newborns; Prenatal care and the (dis)accompaniment of the health professional; Nosological chart - symptoms and manifestations and disorders addressed. Conclusion: it is considered important to include, in discussions and research on women's health, the analysis of the evolution of major mental disorders and their relationships, as a gestational period subsequent to the development of psychiatric symptoms, thus seeking to cover women's mental health in its fullness and not only in the puerperal period. Descriptors: Maternal and Child Health; Mental health; Public health; Women's Health; Mental Disorders; Interdisciplinary Research.

RESUMO

Objetivo: identificar as evidências sobre os aspectos da gestação e puerperio de mulheres portadoras de transtornos mentais em Brasil. Método: trata-se de estudo bibliográfico, tipo revisão integrativa, de artigos publicados entre 1980 e 2018. A busca realizou-se nas bases de dados LILACS, MEDLINE, BDENF e na biblioteca virtual SciELO. Apresentaram-se os resultados em figuras. Resultados: selecionaram-se 19 artigos e, após a leitura crítica, destacaram-se quatro categorias temáticas: Implicações para os recém-nascidos; Pré-natal e o (des)acompanhamento do profissional de saúde; Quadro nosológico - sintomas e manifestações e Transtornos abordados. Conclusão: considera-se importante incluir, nas discussões e pesquisas sobre saúde da mulher, o desenvolvimento de transtornos mentais maiores e suas relações, como um período gestacional posterior ao desenvolvimento dos sintomas psiquiátricos, buscando, assim, abranger a saúde mental da mulher em sua plenitude e não apenas no período puerperal. Descriptores: Saúde Materno-Infantil; Saúde Mental; Saúde Pública; Saúde da Mulher; Transtornos Mentais; Pesquisa Interdisciplinar.

RESUMEN

Objetivo: identificar las evidencias sobre los aspectos de la gestación y puerperio de mujeres portadoras de trastornos mentales en Brasil. Método: se trata de un estudio bibliográfico, tipo revisión integrativa, de artículos publicados entre 1980 a 2018. Se realizó la búsqueda en las bases de datos LILACS, MEDLINE, BDENF y en la biblioteca virtual SciELO. Se presentaron los resultados en figuras. Resultados: se seleccionaron 19 artículos y, después de la lectura crítica, se destacaron cuatro categorías temáticas: Implicaciones para los recién nacidos; Pre-natal y el (des) acompañamiento del profesional de salud; Quadro nosológico - síntomas y manifestaciones y trastornos abordados. Conclusion: se considera importante incluir, en las discusiones e investigaciones sobre salud de la mujer, el análisis de la evolución de trastornos mentales mayores y sus relaciones, como un período embarazoso posterior al desarrollo de los síntomas psiquiátricos, buscando, así, abarcar la salud mental de la mujer en su plenitud y no sólo en el periodo puerperal. Descriptores: Salud Materno-Infantil; Salud Mental; Salud Pública; Salud de la Mujer; Trastornos Mentales; Investigación Interdisciplinaria.

Pregnancy is seen as a period of transition, with different social, physiological and psychological changes for the woman. The psychological changes in various researches are evidenced. In a study carried out with 300 pregnant women, a tool for the evaluation of mental disorders in primary care was presented, in 76 of them, a probable diagnosis of mental disorder, of which 46 had symptoms of depression/dysthymia and 58, of anxiety/panic.1

Despite the psychological changes that are considered common in this period, for this article, women who are already carriers of common and severe psychiatric disorders, such as schizophrenia and bipolar disorder, in addition to anxiety disorders are interested. It is pointed out in studies that it is expected that psychological changes, obstetric complications and even fetal malformations in pregnant women with mental disorders.24 For such cases, multiprofessional attention in the field of mental health that is articulated to the discussions of obstetric care is required, since such a process may be more complex due to neonatal, obstetrical or psychological complications, and may hinder the affective bond between the mother-child binomial.46

On the other hand, there is a variety of research on the puerperal period. It was stated, with regard to the mental disorder of the puerperal women, by a study, 7 that puerperal dysphoria occurs in 50% to 85% of the women, constituting a transient and mild picture that usually does not require treatment; postpartum depression has a prevalence of around 13% and should be treated because it can cause negative repercussions on mother-infant interaction and other aspects of a woman’s life; and postpartum psychosis is rare, appearing in about 0.2% of puerperal women.

It identifies a gap in undergraduate and specialization courses, which do not include the study of common and severe mental disorders in pregnant women in their curricular matrices. As a reflection, the mental health care during the gestation and puerperium of women with mental disorders is often inadequate, without appreciation and respect for their legal rights.89 It reaffirms the need to discuss broadly and multiprofessionally the ethical aspects and the assistance provided to women with mental disorders.10 It is also necessary to stimulate research that correlates technologies and advances in the area for the better management of these users.

OBJECTIVE

- To identify the evidences on the aspects of gestation and puerperium of women with mental disorders in Brazil.

METHOD

It is a quantitative, bibliographical study, type integrative review of scientific articles published in the period between 1980 to 2018. It seeks, in the integrative review, to promote the practice based on scientific evidence, synthesizing conclusions through independent studies with the same theme, thus requiring a rigorous analysis of data.11 It is also aided in decision-making as well as in the discussion of practices used.

Six stages were followed for this integrative review. The first one was the identification of the topic to be addressed, which deals with the aspects of gestation and puerperium of pregnant and puerperal women with mental disorders, and the research question: “What has been investigated and published about gestation and puerperium of women with mental disorders?”.

The criteria for inclusion and exclusion of the studies were established in the second stage. Inclusion criteria were considered: Brazilian publications available in full and dated from 1980 to 2018. It is reported that the time cut considered the year of construction and implementation of the Integral Women’s Health Care Program (IWHCP) in 1983. It elaborated for the collection of data, a form containing: title, year of publication, purpose, place of research and main considerations.

Studies that were unavailable in their entirety and internationally were excluded, considering only the Brazilian context in this research; however, a study carried out in Brazil was published and published in an international journal. Theses, dissertations, editorials, review articles and gray literature were also excluded, since they did not meet the focus of this review.

The literature search was carried out in Latin American and Caribbean Literature in Health Sciences (LILACS), Medical Literature Analyzes and Retrieval System Online (MEDLINE) and Nursing Database (BDENF) and Scientific Electronic Library Library Online (SciELO). The keywords and descriptors (DecS / mESH) used in Figure 1.
Thus, from the application of the inclusion and exclusion criteria, 19 articles were included and analyzed, as shown in figure 2.

An instrument was prepared in the third stage to collect and define the information presented by the publication: authors, journal, article title, year of publication, place of research and main considerations. During the fourth stage, the instrument and its data were filled out and analyzed by careful reading of the publications, thus generating five thematic categories. The fifth stage was characterized by the analysis and discussion of the data. The sixth stage was the publication and presentation of the results.

**RESULTS**

19 articles were selected for analysis in this integrative review, four (21.05%) published in 2012; two (10.53%) in 2016; (10.53%) in 2011 and only one (5.26%) in the other years (1998, 2002, 2005, 2006, 2007, 2009, 2010, 2014, 2015, 2017 and 2018). Although the inclusion criterion covers the search until 1980, it is revealed that the
Teixeira CS, Barbosa TL, Marangoni VSL et al.

oldest article found was from 1998, after 15 years of construction and implementation of the IWHCP.

As regards the area covered by the journals responsible for publications, five (26.32%) articles were published by Public Health Booklets. Nursing journals (five journals) were discreetly present, considering that it is a profession that is closely linked to the care of pregnant and postpartum women, and of the ten journals, two were aimed at studies in the area of mental health.

It is pointed out that ten (58.63%) come from the Southeast region, while five (26.31%) from the South; (10.53%), from the Mid-West and two (10.53%), from the Northeast, with no representation of the North region (Figure 3).

After the reading and analysis of the articles, the articles were categorized into content units, being grouped into four themes that characterize the aspects of gestation and puerperium of women with mental disorders: Implications for newborns; Prenatal follow-up; Nosological chart - signs and symptoms and disorders addressed.

♦ Implications for newborns

It is evidenced that the themes related to this category reveal that the presence of maternal mental disorders can determine perinatal or postnatal complications in newborns and, among the complications, we can mention: prematurity, fetal malformations, low birth weight and difficulties in breastfeeding.4,14

It was observed the presence of worse perinatal outcomes in pregnant women with schizophrenia, however, mothers with depression diagnosed in the second trimester of pregnancy and presenting symptoms of anxiety presented a strong relation with prematurity and low weight.1,16

It is proposed, in a study carried out in the Southeast, 28 the hypothesis that minor impairments of maternal mental health, even if not incapacitating for child care and related to precarious living conditions, could provide negative outcomes, including malnutrition.

Some behaviors have also been observed in pregnant women, such as the use of tobacco and alcohol during pregnancy, often generating a harmful triad to fetal development composed by the abuse of harmful substances, risk factors and low pre-natal follow-up index.15,25

It is also mentioned in the literature that the risk of children of mothers with major mental disorders presenting congenital malformation is 63% higher when compared to that of children of mothers without mental disorders, such a contribution contributing to the association between risk of congenital malformation and maternal mental disorders.4

They relate the early interruption of breastfeeding, the insomnia of the child and its difficulty to feed on the maternal depressive symptoms.14 It is mentioned that mothers who present depressive symptoms or develop negative meanings related to the child end up voluntarily interrupting breastfeeding, since they seek to avoid the creation of affective bonds.22

Maternal cortisol levels are increased in depression and in stress-related disorders, which may lead to fetal prematurity, since this hormone is related to the maturation of the central and pulmonary nervous system, acting on the synthesis of surfactant.30

It should be pointed out that another issue that has been constantly addressed was the decision on pharmacological treatment, since these drugs present a risk of teratogenicity and neonatal toxicity, since they exceed the placental barrier, however, pharmacologically untreated mental disorders may present obstetric risks and major neonates.16,18 The decision must be made jointly, without excluding the woman, clarifying all the risks and side effects.31

As an alternative to pharmacological treatment, which is often abandoned by women who find themselves pregnant, psychotherapy has been instrumental in preventing relapse and worsening of depressive symptoms, and the cognitive realignment provided by psychotherapy assists in negative feelings related to the newborn.32

♦ Prenatal care and the (dis) accompaniment of the health professional

During the analysis of this category, it was identified that the studies17,19,26 evidenced the low adherence of the pregnant women to prenatal care and that the women who are part of the studied population do not know which public health service to look for.

It is inferred in the surveys analyzed that 20-1,25 that the majority of women did not perform satisfactory prenatal follow-up. The need for prenatal follow-up is based on the idea that major mental disorders may have consequences for the future of this mother-baby binomial, since residual symptoms may be present in the long term.24

It is reported that professionals still have difficulty identifying women who may be in postpartum depression. It is also reiterated that, during prenatal care, the focus remains on the physiological aspects of gestation, with few
Teixeira CS, Barbosa TL, Marangoni VSL et al.

strategies for the identification of women at higher risk of developing puerperal mental disorders.24

The Basic Health Unit (BHU) should be the beginning of the line of care in the care trajectory of this pregnant woman, however, what was identified in the previously mentioned research was the lack of preparation of the professionals to deal with adverse situations, such as symptomatology, psychological contribution and pharmacological treatment. As regards the support provided by the Psychosocial Care Centers (CAPS), it is verified that the professionals of these institutions do not know how to deal with sexuality and family planning of women with mental disorders.17

It was also noted the need for family planning policies that play a significant role in the CAPS, since these women have high rates of unplanned pregnancies and are more susceptible to sexual abuse. It is demonstrated, in a study carried out in Ceará, that the professionals of the CAPS are unfamiliar with the subject and that they need institutional support to develop activities aimed at the family planning and reception of these women.17 It is necessary, therefore, to have prenatal care that is capable of identifying and conducting these cases, training the multiprofessional team, valuing discussions about appropriate and integrated care to the network, using all the devices of the health system.27

It is recalled that, currently, teams can use scales and instruments that assist in assessing the mental health of this woman, and programs such as psychological prenatal care, with emphasis on psychoprophylaxis, can aid in the detection of symptoms and risk factors for the development or worsening of a mental disorder.44

♦ Nosological chart - symptoms and manifestations

The predominant characterization of depressive symptoms was observed in relation to the nosological picture cited in the studies analyzed, and this fact was already expected, since depression remains as a mental disorder most studied in the gestational period.

It is suggested that, due to the appearance of depressive symptoms before pregnancy, an increased risk factor for the development of postpartum depression.13,17,24 It was found that low-income women classified as obese had a greater association with common mental disorders, and stressful events or psychosocial difficulties may also predispose the appearance of more severe symptoms, such as outbreaks and crises.26

It is known that depression can also cause more severe pictures in the relationship of mothers with their newborns and, in cases of delusions or crises, they may see the child in a negative way.21-2 It was observed the association of postpartum depression with a history of depression or other psychiatric treatments.13,22

It was found in one study 25 that young pregnant women presented more symptoms of anxiety and depression, however, suicidal ideation was more frequent in those who were not pregnant. The factors associated with being lack of affective maturity, difficulties in family and affective relationships, and the transition between childhood and adulthood.35

The prevalence of suicide was 11.5%. It is emphasized again in the study that the follow-up remains in the physiological model, with little follow-up of the mental health of these women.19

It is mentioned that the most common symptoms found during the puerperium were: affection impaired, attention deficit and hostility. There were few studies that analyzed the evolution and the symptomatology of these disorders, as well as there are no studies that relate the presence of psychotic disorders and the outcomes or obstetric complications.22

♦ Approached disorders

The most frequent mental disorders in the articles were discussed. There was a clear predominance of articles dealing with postpartum depression, 11,14,6,21-3,28 as well as the lack of research on pre-gestational mental disorders, and this scenario prompts reflections on difficulties with that these women are assisted and monitored throughout the pregnancy-puerperal period.

The prevalence of acute psychotic conditions in pregnant women in the psychiatric emergency department and in the obstetric clinic of the Hospital das Clínicas of the University of São Paulo was reported, and researches such as this facilitate the identification of pre-gestational mental disorders.28

Common mental disorders (CMDs) were also addressed frequently. It is noteworthy that CMDs are characterized by symptoms such as insomnia, fatigue, depressive signs, which do not meet the diagnostic requirements in the Diagnostic and Statistical Manual of Mental Disorders (DSM-V), but cause functional incapacity in the individual.12,23,26

It was found, a high prevalence of CMD and an important relation with female self-esteem in a sample of pregnant women.23 The relationship between CMD and postpartum depression has been discussed in some studies, since there is a relationship between the onset of CMD during pregnancy followed by depression in the puerperal period.36

**DISCUSSION**

The results point to the need for more studies that analyze and characterize the woman with
mental disorder and her care walk during pregnancy and the puerperium. It is the performance of trained professionals who can welcome and assist this pregnant woman, which is of fundamental importance for the definition of care lines, and many international studies address the neonatal outcomes, the appropriate management and the various specificities of this population. It is revealed that, currently, this population remains in the Unified Health System in two lines of attention: obstetric and mental health, however, even after reformulation of obstetric care from the implementation of the Stork Network and restructuring of health mental and, after years of struggle for the Psychiatric Reform and social insertion of patients with mental disorders, it is observed that there is no point of discursive intersection that problematizes and sustains the humanized and specialized care for those with major mental disorders during their gestational and puerperal period. In this sense, it is observed that public health policies follow their own course without an integral vision. The mental health care line is usually only activated in an emergency.

In this sense, it is understood that there is no need for a specific flow chart, given that they must have access to care in the various points of the network, justifying the universalization of health. Appropriate care should be available in psychosocial care centers, in basic health units or in outpatient high-risk prenatal outpatient clinics, however, the low adherence of pregnant women to prenatal care may indicate fragilities in the care of this population in particular, signaling the need for greater definitions of the care process that these teams provide in attention to this demand. It is emphasized that the national findings are in line with international results. However, it is mentioned that the international studies are presented in greater quantity and specificity, which evidences the necessity of this subject being investigated in Brazil. It is assumed that there is insufficient data or discussion to characterize and adequately assist this population of women and newborns, who follow the Unified Health System without proper care.

The postpartum depression was expected to be highlighted, since the focus of female mental health is usually directed towards the puerperal period; however, this may be considered detrimental to the understanding of the evolution, symptomatology and perinatal outcomes in pregnant women who already had a mental disorder.

It is questioned the low frequency of studies that relate schizoid disorders, since many are based on genetic and behavioral theories, and such studies would be of great scientific value for the characterization and support of this population. Although schizophrenia and other psychotic disorders are closely related to fetal malformations, there are no conclusions about the subject, however, the relationship between obstetric complications, mental disorders and psychoactive drugs deserves attention and further studies that thematic crises and outbreaks may occur as psychiatric complications that develop into obstetric complications; for example, an international study reports the case of a mother who requested a cesarean section prematurely, since she had suicidal thoughts. It is pointed out that another point to be discussed is prenatal monitoring, seen as essential to prevent and assist intercurrences during and after gestation. It has been stimulated, through many ministerial actions, to join prenatal care in the first trimester. However, among the indicators of the Ministry of Health for the guide line of the Stork Network, there is still no priority indicator that addresses mental health or psychosocial care for pregnant women and postpartum women. At least eight antenatal consultations are recommended by the World Health Organization (WHO) in the 2016 guidelines, with the aim of reducing perinatal death and improving the experience of care for these women. It is indicated in the Primary Care Booklet, which describes the attention to low-risk prenatal care, that cases of psychiatric illness and those requiring follow-up should be referred to high-risk prenatal care.

It is demonstrated by the prevalence of gestational depression in adolescent pregnant women, when compared to adult pregnant women, the importance of prenatal follow-up with psychological support. It is noted that young people in this situation often seek acceptance, needing a support link during pregnancy, and sensitize this adolescent about the importance of identifying depressive signs or low auxiliary self-esteem in the psychophrophylaxis of depressive disorders. In this sense, the psychological prenatal program, carried out in Brasília, characterized by the differentiated methodology, as objectives, the promotion of the humanization of the gestational phase and the construction of parenthood, and such methodologies could be used as tools, both in basic care and in hospital care, for the detection of symptoms indicative of mental disorders.

In addition, hormonal synthesis and its relation to the psychological changes of the pregnant woman should be considered. It is known that recognized hormones of physiological changes in pregnancy are also responsible for psychological variations, especially estrogen, progesterone, prolactin and oxytocin, so that patients with...
mental disorders may present with signs and symptoms."}

Estrogen and progesterone are closely linked to mood reactions and depressive disorders, predominantly their relationship to anxiety disorders. It is based, by the unexpected fall of these hormones in the puerperal period, a theory on the etiology of the postpartum depression.34,37 Oxytocin, also known as the "love hormone," is known for the promotion of uterine contractions and also acts on breastfeeding and the sensation of pleasure during sexual intercourse. It is noted that low levels of oxytocin can cause anxiety, maternal aggression and damage to social cognition.5

It is reported that other substances, such as somatostatin, neurotensin and vascular endothelial growth factor, act doubly in the central nervous system and placenta, however, no national studies have been found that focus on the relationship of these substances with changes or specificities of the pregnancy period, again reinforcing the importance of discussion and investment in studies on the subject.4

It is of the utmost importance to contemplate women's mental health in their fullness, since studies on the puerperal periods end up excluding symptoms and pre-existing conditions and limit women's mental health to the function of generating and caring.

**CONCLUSION**

It is important to emphasize the importance of preparing professionals during reception and reception, in view of the aspects of gestation and puerperium of women with mental disorders as evidenced in the literature. It is noticed, initially, that the absence of problematization leads us to think about the importance of structuring a specific care line for women with mental disorders during their gestational and puerperal period. However, this unilateralised understanding could reinforce the idea of obstetric care manicomication. Considering the current scenario of regression of public mental health policies, it is observed that the risk of stigma and institutionalization of people with mental disorders.

It is advocated, therefore, the construction of integral obstetric care, with professionals sensitive to psychosocial issues, since the reception and the humanization of the professionals can help in the good emotional development of the woman and a better prognosis. It would be promoted by the characterization and insertion of this woman in obstetric care plans, better discussions about alternative treatments, follow-up during prenatal care, and help identify neonatal outcomes.
