EXPERIMENTAL STUDIES DEVELOPED BY BRAZILIAN NURSES: INTEGRATIVE REVIEW

ESTUDOS EXPERIMENTAIS DESENVOLVIDOS POR ENFERMEIROS BRASILEIROS: REVISÃO INTEGRATIVA

ESTUDIOS EXPERIMENTALES DESARROLLADOS POR ENFERMEROS BRASILEÑOS: REVISIÓN INTEGRADORA

Priscila Moreno Sperling Cannavan¹, Roberta Nazario Aoki², Angélica Olivetto de Almeida³, Luciana Aparecida Costa Carvalho⁴, Luara de Carvalho Barbosa⁵, Giselli Cristina Villela Bueno⁶

ABSTRACT

Objective: to describe the national production of Brazilian Nursing experimental studies published in the last five years. Method: integrative review conducted in the MEDLINE, Embase, CINAHL and Scopus databases and in the Virtual Health Library. For the search strategy, the following descriptors were used: "Controlled Clinical Trial", "Clinical Trial", "Randomized Controlled Clinical Trial" and "Nursing Research". Included were: original articles published between the years 2015 and 2020, in Portuguese, English and/or Spanish, with nurses as first author and with a score of five in the Jadad. Results: a total of 16 articles were analyzed, with a score of five on the Jadad scale, which contemplate three premises: randomization, blinding, and adequate description of losses. Four major areas of knowledge were identified: integrative practices, adult and elderly health, maternal and child health, and stoma therapy. In the theme of integrative practices, the studies demonstrated the effectiveness of these practices, while in the area of adult-elderly and maternal-infant health, studies of educational interventions prevailed; stoma therapy studies addressed topical therapies that assist in the process of tissue healing/prevention of skin lesions. Conclusion: it was identified that the main focus of studies with the experimental method by Brazilian nurses belonged to four major areas of health knowledge and addressed educational issues and clinical interventions in Nursing practice. Descriptors: Controlled Clinical Trial; Clinical Trial; Nursing Research; Review; Nursing.
RESUMO

Descritores: Ensaio Clínico Controlado; Ensaio Clínico; Pesquisa em Enfermagem; Revisão; Enfermagem.

RESUMEN

materno-infantil y estomaterapia. En el área de prácticas integradoras, los estudios demostraron la efectividad de estas prácticas, mientras que, en el área de salud adulto-anciano y materno-infantil, prevalecieron los estudios de intervenciones educativas; Los estudios de estomaterapia han abordado terapias tópicas que ayudan en el proceso de curación de tejidos/previsión de lesiones en la piel. **Conclusión:** se identificó que el foco principal de los estudios con el método experimental de los enfermeros brasileños pertenecía a cuatro grandes áreas del conocimiento en salud y abordaron cuestiones educativas e intervenciones clínicas en la práctica de Enfermería.

**Descriptores:** Ensayo Clínico Controlado; Ensayo Clínico; Investigación en Enfermería; Revisión; Enfermería.

**INTRODUCTION**

Research in Nursing comes from the 1930s with the dissemination of the category through reflections and experiences in congresses and the first national journal "*Annaes de Enfermagem*". From the 1960s, with the university reform, graduate courses were instituted with the objective of articulating teaching and research and promoting, disseminating, and encouraging research since graduation. The support of the Brazilian Association of Nursing (ABEn) was fundamental for the diffusion of scientific production in its congresses and scientific meetings.1

In the trajectory of Nursing research, it is observed that the first studies presented descriptive methodologies, experience reports, and expert opinions. As of the 1980s, studies related to Nursing care and standardization of techniques were incorporated, mostly quantitative studies.2 Only in the 1990s, research with other methodological approaches was added.1

Nurses are expected to develop research methods that enable effective nursing and make it possible to apply the results directly to health care.3 Clinical trials promote
outcome-based clinical practice with an impact on the quality of intervention-based nursing care.\textsuperscript{4}

The area of clinical research for nurses has great potential for development,\textsuperscript{5} however, changes are still needed in the qualification of this professional to act, as well as the understanding of his participation in clinical studies. The development of this knowledge projects the profession and contributes to the development of different fields of action.\textsuperscript{6}

The growth of scientific production in Brazilian Nursing in the last three decades has impacted the development of knowledge in its area of activity, which, in turn, has followed global trends, reflecting advances related to the actions of care, teaching and, consequently, the demands for research in the area.\textsuperscript{7} Nursing emerges with greater visibility, recognition and consolidation as a science.\textsuperscript{6}

A recent scoping review presented data of randomized clinical trials from 2009 to 2016 in Nursing journals worldwide, with the description of a production of approximately 40 studies per year, with emphasis on the increase in the production of clinical and quasi-experimental studies in Asia and Europe, with 118 and 112 publications, respectively. In the Americas, 92 studies were produced, with only ten identified as originating from Brazilian Nursing.\textsuperscript{8}

The development of experimental research in Nursing is not common, unlike observational studies, especially descriptive ones, which are conducted more prevalently. The use of clinical research is challenging to evaluate care practices, besides strengthening evidence-based practice in national Nursing, which is still incipient.\textsuperscript{9-10}

Currently, there are no guidelines or consensus around the ideal path that should be followed to develop a robust methodological framework. The authors believe that future frameworks will be developed, providing best practices.\textsuperscript{11}

Another concern, present in developed countries, is to measure and measure the impact of research. It is an essential exercise to direct the allocation of limited research resources, to maximize benefit, and to help minimize waste.\textsuperscript{11}

When experimental studies aim to improve clinical practice, the benefits are extended to patients and society, supporting an improvement in clinical care and health promotion policies.\textsuperscript{12}

Nursing research is advancing, presenting well-designed clinical trials with more reliable evidence for health interventions\textsuperscript{13}, but still far from the scenario presented in other countries. It becomes relevant to present a study to identify and describe the national Nursing production that addresses experimental studies.
OBJECTIVE

To describe the national production of Brazilian Nursing experimental studies published in the last five years.

METHOD

This is a bibliographic, descriptive, integrative literature review study, which aims to synthesize research results on a given subject and point out existing gaps that can be filled with new research.¹⁴-¹⁵

To prepare this study, an integrative review was conducted and the following steps were followed: identification of the theme and formulation of the research question; selection of criteria for inclusion and exclusion of studies; definition of the information to be extracted from the selected research; categorization and analysis of the studies; interpretation of results and synthesis and exposure of data.¹⁶

In the first stage, the research question was established: "What studies with the experimental method have been conducted by Brazilian nurses in the last five years?" After defining the guiding question, the other stages were initiated.

In the second stage of the review, the criteria for inclusion and exclusion were established and represented requirements for inclusion: publications from the period 2015 to 2020; articles published in Portuguese, English and Spanish originating in Brazil, in their entirety, addressing the conduct of experimental studies, which were published by nurses as first author and scored five in the Jadad score.

Jadad's instrument, used to ensure rigor in the analysis of experimental studies, assesses three aspects of clinical trials: randomization, blinding, and description of losses to follow-up. It is composed of five questions and results in a score ranging from zero to five.¹⁷ Studies with a score below three are considered to be at high risk of bias.¹⁷ Studies that scored five on the Jadad score were included.

The exclusion criteria were: 1) theses and dissertations, book chapters, literature reviews and editorials; 2) articles with only abstracts available.

In the third phase of the study, the primary source databases MEDLINE, Embase, Cumulative Index to Nursing and Allied Health Literature (CINAHL), Scopus, and the VHL electronic portal were consulted. A combination of descriptors was used to maximize the search. The descriptors used, extracted from the Health Sciences Descriptors (DeCS/Bireme) and Medical Subject Headings (MeSH), and the combinations were: "Controlled Clinical Trial OR Randomized Controlled Clinical Trial AND Nursing Research"
and their respective synonyms (Figure 1). Synonymous terms, suggested by Embase at the time of the search, were also searched.

Figure 1. Sources consulted and respective search strategies. Campinas (SP), Brazil, 2022.

The strategies adopted for locating the articles were adapted from the PRISMA recommendations\(^{18}\) and represented in the flowchart of the steps developed in this review in order to answer the research question.
In the next step, corresponding to the phase of identification of the information to be extracted, the following variables were collected: first author; year of publication; title;
population; study development setting; intervention; recommendations/conclusions; category.

In the penultimate phase, the interpretation and compilation of the main findings was carried out and, finally, the results were presented in four categories.

RESULTS

A total of 4404 articles were identified in the databases, 2737 in VHL, 945 in Embase, 370 in MEDLINE, 177 in Scopus, and 175 in CINAHL. Duplicates were removed and the reference managers EndNote and Rayyan were used to help in the selection. The EndNote manager was used in the first stage of selection, in which all selected articles were grouped in a single file and duplicates were searched for. The Rayyan manager was used for the blind selection of articles, carried out independently by two researchers.

A total of 454 studies were excluded for duplicity, resulting in 3950 documents. Then, the titles and abstracts were read, and 3815 were excluded because they did not meet the inclusion criteria. Subsequently, after a complete and thorough reading and analysis using the Jadad instrument, 119 more studies were excluded for scoring below five on the scale, resulting in a final sample of 16 articles.

For the characterization, the studies were organized in Excel® spreadsheet in descending order, considering year of publication, first author, title, intervention studied, results, recommendations and conclusions, presented in figure 3.

The results were categorized according to the research focus and the following study themes were found for the analysis of the results: 1 - adult and elderly health; 2 - maternal and child health; 3 - integrative practices; 4 - stoma therapy.

DISCUSSION

True experimental studies are those in which the sample is randomized, the variables are controlled, and there is a control group and an intervention group, including manipulation of a variable to examine the direct cause or predictive relationship between the variables, excellent for demonstrating cause-effect.36

Despite the requirements of an experimental study, there are variables regarding its wording, method, and demonstration of results. It is important to analyze the quality of the published papers, among the requirements for a quality experimental study, which must contain a description of the randomization, the follow-up of groups and losses of follow-up, in addition to the blinding of the researcher and participants.17

In the review, among the 135 articles entitled experimental, only 16 demonstrated optimal quality according to the instrument built by Jadad (maximum score equal to five), that is, studies with adequate randomization and blinding and description of dropouts or losses. Thus, it becomes evident the difficulty of a study, in health, to cover all the requirements to achieve maximum quality and, consequently, better evidence.17

Among the main causes pointed out as difficulties in the execution of an experimental study are adequate randomization and blinding of interventions. Many interventions permeate ethical issues, because often the participant and/or the researcher cannot be blinded, that is, they cannot obtain knowledge about which group the intervention is in. This occurs mainly when the effectiveness of some intervention is tested, especially when the literature already demonstrates some benefit in its application, and it is not ethical to offer it to only some individuals.37

In addition, the complete description of the methodology employed must be rigorously followed, and the use of some instrument or protocol that evaluates the quality of the type of study developed, assisting in its planning, execution and description is indicated.17

In this study, four major areas of knowledge were identified, among them, integrative practices (six studies),23,26-27,29-30,34 health of the older adult (four studies),20,22,31,33 maternal and child health (four studies)21,28,32 and stoma therapy (two studies).25,35

This result 23,26-27,29-30,34 can be justified by the increased use of integrative and complementary health practices, which were included in the National Policy of Integrative and Complementary Practices of the Ministry of Health (PNPIC/MH) in 2006. From this inclusion, their use has been increasing and, consequently, studies that prove their efficacy, through methods capable of demonstrating the cause and effect relationship, should be encouraged. Thus, Nursing can justify the importance and applicability of integrative practices through studies that result in better evidence.38

Acupuncture and auricular acupuncture were used as a method of pain control,23 blood pressure27 and stress30 and, in this study, have proven to be effective and, within Traditional Chinese Medicine, are the most applied, highlighting the positive results of this Nursing intervention for several objectives as a complementary therapy. The identification of these studies becomes relevant, confirming the findings of previous studies.39-41

Music therapy, herbal therapy, and relaxation therapy were effective in reducing stress and anxiety. Acupuncture, music therapy, Reiki, Yoga, and auriculotherapy are the most used practices for treatment and coping for reducing stress, anxiety, depression, hypertension, reducing blood glucose, weight, and promoting well-being. The findings of this study corroborate the literature and reinforce the benefits of each practice through studies with high scientific rigor, reinforcing evidence-based Nursing interventions.42
Adult and maternal and child health had eight studies in total. Both offer educational interventions for specific populations, reinforcing the role of nurses as educators, highlighting the effectiveness of their educational interventions, being carried out through various approaches, such as pedagogical guidance during the nursing consultation, home care, counseling with motivational dynamics and educational sessions with playful strategies.

Evidence shows that most studies involving educational strategies in nursing need greater methodological rigor, however, there is a growing tendency for controlled and randomized studies. The nurse plays a relevant role in health education, thus, studies that demonstrate accurate results may allow the establishment of the cause-effect relationship in nursing educational actions.

As for the area of stoma therapy addressed the use of topical products for treatment/prevention of skin lesions (radiodermitis and chronic foot ulcer), however, the management of this type of injury is not exclusive to nurses with specialization in stoma therapy, and these studies are extremely relevant for nurses from various areas. In addition, they can be used as a methodological reference for other studies.

Thus, from this study, studies with high methodological rigor were identified, allowing the scientific validation of Nursing interventions. In addition, they can be used as a theoretical reference for other studies and, probably, may help to improve the quality of care offered.

As a limitation of this work, we observed the absence of previous research on the theme and the scarcity of Brazilian articles that address experimental studies. In addition, some of the studies found did not present detailed methodological design or did not comply with ideal blinding methods.

**CONCLUSION**

It is concluded that in the last five years, 16 articles were published with the complete experimental method (randomization, blinding and description of losses) by Brazilian nurses, focusing on four major areas of health knowledge, being identified the integrative practices, health of the adult-elderly, maternal and child health and stoma therapy.

This study demonstrates the need to expand experimental research with adequate methodological rigor in Nursing. In addition, only four major areas that used this methodology were identified, highlighting the need for this study design in other areas of Nursing knowledge.

The community can use the articles included in this work as a methodological example for future research, as well as the applicability and importance of an instrument that evaluates the quality of randomized clinical trials.

It is believed that, with the expansion of experimental studies, it will be possible to obtain decision making through evidence with high methodological rigor, strengthening the care practice of nurses and promoting greater quality in care.

**CONTRIBUTIONS**

All authors contributed equally in the conception of the research project, data collection, analysis and discussion, as well as in the writing and critical review of the content with intellectual contribution and approval of the final version of the study.
